Morbidity and Mortality

Weekly Report

U. S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE PUBLIC HEALTH SERVICE

Prepared by the

COMMUNICABLE DISEASE CENTER

634-5131

For release July 19, 1963

ATLANTA 22, GEORGIA

yd1. 12, No. 28

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND DEATHS IN SELECTED CITIES FOR WEEK ENDED JULY 13, 1963

POLIOMYELITIS - Eleven cases of poliomyelitis, including 8 paralytic, were reported for the week ending July 13, 1963. This is well below the total of 25 cases (14 paralytic) for the corresponding week in 1962. The figure on page 230 demonstrates the comparative incidence of poliomyelitis through the 28th week in 1958, 1960, 1962, and 1963.

Three cases reported this week from Alab'ama included one from Walker County where there have now been four cases, all paralytic, with onsets of illness between June 3 and July 2. The two cases from Pennsylvania are from the Carlisle area (Cumberland and Perry Counties) where 21 cases have occurred. Mass community programs were conducted in the Carlisle area in late June, with Type I oral polio vaccine (See MMWR, Vol. 12, pp. 205 and 221). A total of approximately

102,000 doses of vaccine were dispensed in the two-county population of approximately 150,000.

Two cases of poliomyelitis occurred in widely separated areas in Tennessee. Single cases occurred in four other States, including Wisconsin, South Carolina, Mississippi, and Oregon.

Cumulative totals for the first 28 weeks of 1963 and the preceding four years are shown in the table below, together with the most recent six week totals:

Poliomyelitis (Cumulated Weekly) 1st Through 28th Week

EPIDEMIOLOGICAL REPORTS

Typhaid Fever - Pennsylvania

From July 3 to July 12, 1963, twenty-three cases of clinically diagnosed typhoid fever were reported to the Pennsylvania State Department of Public Health. Each of the 23 cases attended one of two sessions of a religious encampment in Franklin County, Pennsylvania. The first session was held June 16 - June 29 and the second July 8-12. The camp was not operative during the interim.

The majority of cases reported had attended the first encampment, which included 155 children and 20 adults. Although most who attended were Pennsylvania residents, it is known that several resided in Virginia, West Virginia and Florida, and perhaps other States as yet not known. At present, 10 patients are hospitalized in South-Central Pennsylvania hospitals.

This preliminary report is included to alert the States to this possible source of typhoid fever in campers who may have returned from the Franklin County, Pennsylvania, area.

(Reported by Dr. W. D. Schrack, Jr., Director, Division of Communicable Disease Control, State Department of Health, Pennsylvania.)

Salmonella derby Epidemic - Follow-up Report

The interstate epidemic of hospital-associated Salmonella derby infections, first noted in March, continues. (See MMWR Vol. 12, pp. 220, 199, 182, 173, 167, and 159). From March 1 to July 8, a total of 775 isolations of S. derby has been reported from 25 States and the District of Columbia. (Table 1). Of these, 601 have

of infection in 5 different hospitals.

** At least 3 casas represent infaction acquired from contaminated turkey roll.

been classified as "hospital-associated" infections and have occurred in 40 hospitals in 10 States. The problem is concentrated largely in the Northeastern portion of the country. During this same period there have been 71 infections classified as "community acquired." These have been reported from all parts of the country. Their frequency has been comparable with the normal endemic incidence of *S. derby* isolations (approximately 20 per month).

Since the epidemic began, 16 fatalities have been reported among patients from whom S. derby was isolated (Table II). Most of these patients were suffering from serious debilitating or life threatening diseases; however, in at least one instance the Salmonella infection was considered "a highly contributing" factor in the patient's death.

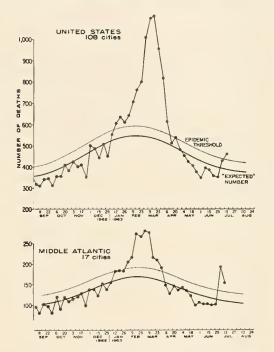

TABLE 2 FATALITIES ASSOCIATED WITH THE ISOLATION OF S. DERBY DURING HOSPITALIZATION

	STATE	AGE AND SEX OF PATIENT	OTHER DIAGNOSIS

13.	Pennsylvania	F	Fractured hip
14.	Pennsylvania	74 F	Renal failure, hepatic failure
15.	New Yark	30 F	Hadgkins Disease
16.	New Yark	59 M	Carcinama bladder

In each of the involved hospitals a consistent epidemiologic pattern has been observed. The initial isolations have been recognized among patients with gastro-intestinal disease, often post operative and usually during the second week of hospitalization. Multiple cases have appeared in widely separated parts of the hospital within relatively short intervals of time. (Continued on page 236)

PNEUMONIA-INFLUENZA DEATHS

The number of pneumonia-influenza deaths reported for all ages by the 108 cities exceeded the epidemic threshold and is mainly due to the increases above epidemic levels reported for the past two successive weeks by the Middle Atlantic States as shown in the figure. Increases in the number of pneumonia-influenza deaths during the past week were also reported by the West North Central and Mountain States. The increase in the Middle Atlantic States followed a moderate heat wave.

SUMMARY OF DEATHS AMONG PERSONS 65 YEARS AND OVER IN 108 U. S. CITIES

The weekly average number of deaths among persons 65 years and over in 108 cities for the four-week period ending July 13 was 6,413 as compared with an expected weekly average of 6,076.

During the first week of the recent four-week period, the number of deaths among persons 65 years and over was slightly below the expected number, but in the second week showed an increase which culminated in an excess

		WEEK E	. 4 Week	Weekly		
	6/22	6/29	7/6	7/13	Tatal	Average
Observed	6,073	6,285	6,331	6,961	25,650	6,413
Expected	6,140	6,094	6,053	6,015	24,302	6,076
Excess	- 67	191	278	946	1,348	337

of 946 over the expected number in the fourth week (ending 7/13). Localization of this excess has been mainly in the Middle Atlantic States.

Morbidity and Mortality Weekly Report

Common sources of infection such as contact with possibly infected persons, exposure in specific locations, common therapeutic or diagnostic procedures or common medications have been notably absent. In some hospitals secondary spread of infection has become a difficult and continuing problem. This has complicated epidemiologic analysis.

The almost simultaneous appearance of these infections in many hospitals in several States clearly incriminated some common source of infection in interstate movement. The following possibilities have been considered: 1) interchange of patients or personnel; 2) use of diagnostic or therapeutic agents; and, 3) dietary items.

Intensive investigations for these possibilities were carried out in 22 hospitals. The first two could be clearly excluded. The third, dietary items, presented a wide range of potentially suspect foods. Histories of foods consumed during the period of 48 hours prior to onset among approximately 200 of the "initial" patients revealed that most were receiving highly restricted diets. Thus many potential food items could be excluded from further consideration. Only one particular item of food was almost universally consumed by the patients. This was raw or undercooked eggs.

Therefore a careful search was made of sources of the eggs supplied to 15 hospitals in 3 States. Among a large number of egg farms identified, only those in two localized geographic areas could possibly have supplied these 15 hospitals. Samples of eggs (235 dozen), pooled chicken droppings (5400 specimens) and poultry feed (58 specimens) were obtained from both areas. S. derby was recovered from one sample of feed and 4 pooled samples of cracked eggs in one of these areas.

Upon review of the data accumulated, the Surgeon General of the Public Health Service released the following recommendation on July 11, 1963:

"There is sufficient epidemiological and bacteriological evidence to suggest that everyone should avoid buying and using cracked or unclean eggs. Persons who are ill, especially infants, the elderly, and individuals suffering from gastrointestinal diseases or malignancies should not be fed raw or undercooked eggs. An undercooked egg is one in which the white is not firm."

"It is recognized that cracked eggs are used for a variety of commercial purposes. So long as eggs used for these purposes are thoroughly cooked and the final product is not recontaminated, there is no inherent danger to the continued use of these eggs for this purpose. Thorough cooking will effectively sterilize the product." (Based on studies conducted by State and local health officials, the Food and Drug Administration, the staffs of numerous hospitals and teams from the Communicable Disease Center.)

INTERNATIONAL NOTES - QUARANTINE MEASURES

Smallpox - Sweden

Two additional cases of smallpox were reported from Stockholm on July 11 and July 12, respectively. One of these, an 89-year-old female patient in a mental hospital, had onset of rash and fever on July 7, 15 days after onset of illness in Case 23, a 73-year-old woman also hospitalized at this institution.

The total number of confirmed cases that has occurred during the outbreak is 25, including four deaths.
